REPORT AND NOTES.

Meteorological. — The meteorological continuous records have been uninterrupted during the year, excepting only the photographic curve of the thermograph during the evening of October 14 for 4 hours, whilst the acetylene gas was being expelled from the pipes by coal gas. The latter has been found to be the more serviceable for general purposes in the Observatory.

The wind is recorded by a Robinson's Anemograph at about 45 feet above the ground. A velocity of 37 miles per hour and over is called a gale.

Bright sunshine is recorded by a Campbell-Stokes Recorder.

The Rain Gauge is a Beckley Self Recorder. Its receiving surface is 22 inches above the ground, and 377 feet above sea-level. The daily measures are taken at 10 a.m. for the preceding 24 hours. *Heavy rain*, noted in the monthly tabulations, signifies a fall of $\frac{1}{2}$ inch or more during the day.

The Barometer is a standard barometer of the pattern approved by the Meteorological Office. It is now mounted, with the photo-barograph, in the underground Magnetic chamber. Its cup is 363 feet above the sea-level. Its readings in the monthly tables are quoted for the density of mercury at 32° Fahr., and for the original position of the barometer at 381 feet above sea-level; and the mean pressures are corrected for diurnal range.

The Thermometers are the property of the Meteorological Office, and are annually compared with the Office-standards. They are mounted at 6 feet above the ground on the north side of the Observatory, enclosed in a Stevenson-Screen. All the readings are corrected for index errors, as determined by the Office-standards.

The *monthly mean temperature* is derived in two ways: 1st, from the mean of the highest and lowest daily readings corrected by the average difference between this mean and the true mean of the hourly tabulations; and 2nd, from the mean of the readings at 9 a.m. and 9 p.m. corrected in the same manner. Both corrections have been furnished by the Greenwich records, and are taken from the well-known Glaisher's tables. The *Adopted mean temperature* is the mean of these two results.

A casual reply to a correspondent, at the beginning of the year, explaining the methods of obtaining the mean temperature of a month, led to the unpleasant discovery that the above corrections had not been applied for some years past, between 1903 and 1906 inclusively. The corrections have, since, been applied; and the following table is inserted to show an example of the resulting mean temperature as obtained *with* and *without* the Glaisher corrections.

MEAN TEMPERATURE.	1882.		
	Jan.	June.	July.
True Mean by Hourly Tabulations	41·1	54·1	57·5
(1) By mean of Max. and Min. <i>with</i> Glaisher correction.....	41·2	55·7	58·6
(2) By mean of Max. and Min. <i>without</i> correction.....	41·4	57·5	60·5
(3) By 9 a.m. and 9 p.m. readings <i>with</i> correction.....	40·6	52·8	56·6
(4) By 9 a.m. and 9 p.m. readings <i>without</i> correction.....	39·9	53·1	56·7
Adopted Mean Temp. <i>with</i> correction...	40·9	54·2	57·6
,, ,, <i>without</i> correction	40·7	55·3	58·6

The three months, Jan., June, July of the table were taken haphazard; and the results show the nearer approach to the true mean temperature obtained by the combined corrected figures opposite (1) and (3) than by the uncorrected figures of (2) and (4).

The preparation of this table led on to a re-examination of the entire series of meteorological entries of the last 60 years. The whole work has been carried out with the utmost care by Br. W. McKeon, S.J.; and the following is his voucher for the results:—

“The whole of the period 1903–6 has been carefully revised and corrected, including the hygrometrical table workings from the corrected data, and also the corresponding figures in the column of 60-year-means. So that now the tabulations of 1907 stand as they would have appeared had these corrections not been omitted,

“Moreover the whole Report has been thoroughly revised. A considerable number of clerical errors, mostly in the quotations of rainfall, and sunshine, and in the sections of Extreme Readings, have been discovered and corrected.

“With regard to the Report in general I may say with confidence that every single error has been expunged, and every figure and statement made, either regarding the year 1907 itself, or the 60 years' period of observation, is perfectly trustworthy.”—W. McK.

Some changes will be found in the form of the monthly tables, and several additional items. A 30 years' table of corrected Rainfall (1878–1907) is given at page 38, as a supplement to a similar table (1848–1877) printed

in the Results for 1878. Curves are added showing the annual variation over 60 years of four meteorological elements—viz., Mean Barometric pressure, Total wind mileage, Mean temperature, and total Rainfall, with a curve of Wolf's Sun Spot Relative-numbers, by Prof. Wolfer, Zurich, and printed in the Monthly Weather Review, April, 1902, of the U.S. Department of Agriculture, Washington.

The year has been, on the whole, an average year for Barometric pressure, Temperature, Rainfall and Wind-force. There have been no marked extremes of temperature, never above 77° Fahr., nor below 20°. The winter months have had their gales of wind:—two in January, one in February, two in March, one in November, and two in December; but nothing exceeding 50 miles an hour, which was reached at 11 p.m. on March 16th. In the summer months occasional distant thunder or lightning was heard or seen; but only one near and severe storm, on July 21, has been recorded.

The rainfall was only 3 inches above the annual average, notwithstanding the heavy fall in June. The wettest months of the year were June, August, December and March; and the finest months were September and April.

June was a most unsummerlike month, with the greatest rainfall, least sunshine, and lowest mean temperature on our June records. It was also a generally windy month, at an average velocity of $11\frac{1}{2}$ miles an hour—the greatest month-average of the year, and without any velocity greater than 29 miles.

Magnetical.—The magnetographs are of the Kew pattern ; but they were built before the introduction of the two-hourly time scale provided now by clock-worked shutters cutting off the light for 4 minutes at the even-numbered hours. For some years, shortly after the instruments were mounted, shutters were provided by an ingenious contrivance of the late Br. Hostage, S.J., worked by a subsidiary weight which was released by the barograph clock at the times of closing the barograph shutter. But it required the inventor to keep the gear in safely working order ; and the apparatus was removed a few years after his death in 1877. The time-scale is now provided with hand screens at 2 p.m., 4 p.m., and 10 a.m., the photographic papers being changed daily at noon.

The value of one centimetre ordinate of the bifilar curve is tested at least once a year by the method of deflections, to keep it at 0·0005 C.G.S. units. It has been for many years quite constant.

On the unifilar curve one centimetre subtends an angular turn of the suspended mirror through 11'·28 of arc ; and the ordinates are read off on a scale of one division to the arc-minute.

Four daily readings are taken from the unifilar and bifilar curves, the highest and lowest, and the readings at 4 a.m. and 4 p.m. ; but the V.F. balance has not yet given results sufficiently reliable for any other quotation than greater or less disturbance.

It has not yet been found possible, with our limited staff, to take hourly readings from the curves, or to observe for absolute measure of force more frequently than once a month.

But the horizontal direction, or Declination, is observed 4 times each month, at approximately equal intervals, and always, when possible, at 4 p.m. These measures have been corrected by the difference between the curve ordinate at the time of observation and the mean of the readings at 4 p.m. The corrections are usually small. They were introduced, beginning with January, in order to eliminate greater variations occasioned by concurrent magnetic storms. The reading of the photographic Base-line is derived monthly from the mean of the 4 p.m. readings compared with the mean of the 4 absolute measures.

No corrections have been applied to the absolute measures of force. The reading of the bifilar base line has been derived each month from the absolute measure of horizontal force and the general mean of the 4 daily curve-readings. These readings were found to give more concordant results, month by month, than those of the actual time-interval during which the experiments for absolute measure were carried out.

Except for occasional losses through variability of the lights, the magnetograph curves have been satisfactory, enough at least for the tabulation, but not all one could wish to see as photographic records. The instruments were dismounted in the middle of October, and readjusted; and the results since then have become all that could be wished.

On the table of magnetic disturbances (page 48) the following remarks may be of service. There is often some embarrassment in assigning the proper note of magnetic condition to the date. Overlapping of indications cannot

be wholly avoided ; and some allowance must be made for the subjective impressions of the Recorder—a variability of personal equation. But the general intention of the table is that a *calm* (c) shall mean a smooth curve; *small* (s) a disturbance noteworthy only as opposed to a calm; *moderate* (m) a disturbance not to be neglected for any comparison with other phenomena, solar or terrestrial, and worth a reference to the original curve; *greater* (g) a decided storm ; and *very great* (v.g) needs no comment.

Corresponding tabulations are sent quarterly to the Meteorological Institute at De Bilt (Holland), for the International Committee on Terrestrial Magnetism. In these the significant notes are restricted to three—0, 1, 2. The general returns from the Bureau show considerable discordance between the interpretations of different authorities ; and it may be well to state the rule followed at this Observatory. The two important notes are held to be 0 and 2 : the former meaning a true calm, and the latter any disturbance worth comparing with other phenomena ; and the intervening note comprises all the rest.

On this list the notes are quoted for the civil day, and may therefore be found occasionally at variance with our own quotations, which are given for the Astronomical day (from noon to noon). It has not been thought well to make any change here ; because the convenience for tabulation is very great, when the curve, started at noon, stands for one day ; and the risk of clerical errors is notably less. For other entries it is only an already established custom that has hindered the adoption of the astronomical day as more suited to registration by curves which can always be started at noon and never at midnight.

Solar and Astro-physical.—The solar surface has been observed on all available days, and 198 drawings of spots and faculae have been added to our collection. On one day only the surface was found quite free from spots.

The mean disc-area of the spots (in units of $\frac{1}{5000}$ th of the visible surface) appears at 5·8; and the mean daily range of magnetic Declination (in minutes of arc) at 14·7. And the following table shows an unexpected revival of solar activity and magnetic disturbance.

Year	1902	1903	1904	1905	1906	1907
Spot area	0·3	1·9	2·5	6·8	4·8	5·8
Declination range...	9·0	11·8	11·9	14·9	14·2	14·7

The greater spots have also been examined, both visually and photographically, with the large grating and with the 12 prism spectroscope.

Work with the two stellar spectrographs (the Hilger compound prism and the Thorp objective prism) has been suspended, pending an examination of the large collection of plates already obtained. But this examination has been rendered impossible by the long and laborious work, already mentioned, upon the meteorological records.

The new heliostat mentioned in our last report, and also a six-inch portrait lens, the gift of Mr. Whitelow, F.R.A.S., of Southport, have been mounted during the course of the year. But regular work with both instruments has been delayed by impediments experienced in the accurate running of the driving clocks. Sir Howard Grubb is surmounting those of the heliostat clock, and the Director, with the friendly help of Mr. Parkinson, of Blackburn, has so far improved the working of the

Equatorial clock, and the adjustments of the Whitelow camera, that probably no further difficulty will be experienced in long and repeated exposures of the same photographic plate to starry and nebulous regions of the sky.

These and other mechanical improvements have occupied a considerable part of the year; and many clear nights have been devoted to experimental work in connection with them.

The following papers were published during the year:—

“The Spectrum of Mira Ceti in December, 1906, as photographed at Stonyhurst College Observatory.” Monthly Notices, R.A.S., 67, 8. June, 1907.

“Note on the Visual Spectrum of Mira Ceti in December, 1906.” *Ibid.*

“On the connection between disturbed areas of the solar surface and the solar corona.” Report of the British Association. York, 1906.

“The variability in light of Mira Ceti and the Temperature of Sun-Spots.” Astrophysical Journal, 26, 2. September, 1907.

“The Stonyhurst discs for measuring the positions of Sun-Spots.” Journal B.A.A., 18, 1. November, 1907.

“Problems of Solar Pyhsics.” “The Observatory,” No. 380. February, 1907.

Large type, greatest and least readings in 60 years.

OBSERVATIONS OF EARTH-MAGNETISM, 1907.

ABSOLUTE measures of Horizontal Magnetic Force have been made once each month, by the method of Vibration and Deflection.

In these observations the same Magnet has been employed from the beginning of the series in March, 1863. The weight of the Magnet with its stirrup is 825 grains, and its length 3·94 inches nearly. Its moment of inertia, measured by the method of vibrations, with and without a known increase of the moment, is 5·27303 to the English foot—second—grain units, at the temperature 35° Fahr., and its rate of increase is 0·00073 for increase of 10°.

The temperature corrections have been obtained from the formula $q(t^\circ - 32) + q'(t^\circ - 32)^2$ where t° is the observed temperature and 32° Fahr. the adopted standard temperature. The values of the co-efficient q and q' are respectively 0·0001128 and 0·000000436.

The induction co-efficient μ is 0·000244.

The correction for error of graduation of the Deflection bar at 1·0 foot is + 0·00004 ft. at 1·3 + 0·000064 ft.

The observed times of vibration are entered in the Table-without corrections.

The time of one vibration has been obtained each month from the mean of twelve determinations of the time of 100 vibrations.

The angles of deflection are each the mean of two sets or readings.

In deducing from these observations the ratio and product of the magnetic moment m of the magnet, and the earth's horizontal magnetic intensity X , the induction and temperature corrections have always been applied, and the observed time of vibration has been corrected for the effect of torsion of the suspending thread; but no correction has been required for the rate of the chronometer, or for the arc of vibration, the former having been always under 1·5° and the latter never over 50'.

The average deflection of the magnet caused by a twist of the torsion circle through 90° has been about $6'7$ of arc.

In the calculations of the ratio $\frac{m}{X}$, the third and subsequent terms of the series $1 + \frac{P}{r^2} + \frac{Q}{r^4} + \text{ &c.}$, have always been omitted.

The value of the constant P was found to be -0.00215 .

The Vertical and Total Forces are deduced from the measures of the Horizontal Force, and the Angle of Inclination or Dip.

All the computations are in English foot—second—grain units ; but in the final table the results are given only in C. G. S. units.

The Dip, or angle between the direction of total force, and that of its horizontal component, has been measured with Dover's Circle, No. 159, once each month by two needles, always when possible on the days of vibration and deflection observations.

The Declination has been observed at the beginning of each week, usually on Mondays at 4 p.m., and is quoted as the angle between the horizontal direction of force and the Astronomical Meridian, measured from the North Point.

The Differential Instruments, or Photo-Magnetographs, are of the same pattern as those at the Kew Observatory, except that the radial distances between the centres of the magnets and the surfaces of the respective cylinders are shorter, and the clock is not provided with an automatic light cut-off, for the time scale. The "cut-offs" are made by hand at the hours 2, 4, and 22 of the astronomical day, to furnish two time marks at each end of the day's curves, the changes being made between 11-30 and noon, civil time.

The scale value of the Bifilar horizontal force torsion balance, has remained very constant at 0.00051 C. G. S. for one centimetre, during the last seventeen years.

The scale value of the Unifilar Declination Magnet is $11'28$ arc per centimetre.

DATES OF MAGNETIC DISTURBANCES.

The disturbances are divided generally into three classes, *small*, *moderate*, and *greater*; these are indicated by the initial letters of the classes, and the letter *c* denotes *calm*. Very great disturbances are marked *vg*. The days are reckoned astronomically from noon to noon.

Monthly Variation in four Meteorological Elements, 1907.

The dotted curves show the mean values for the last *60 years.

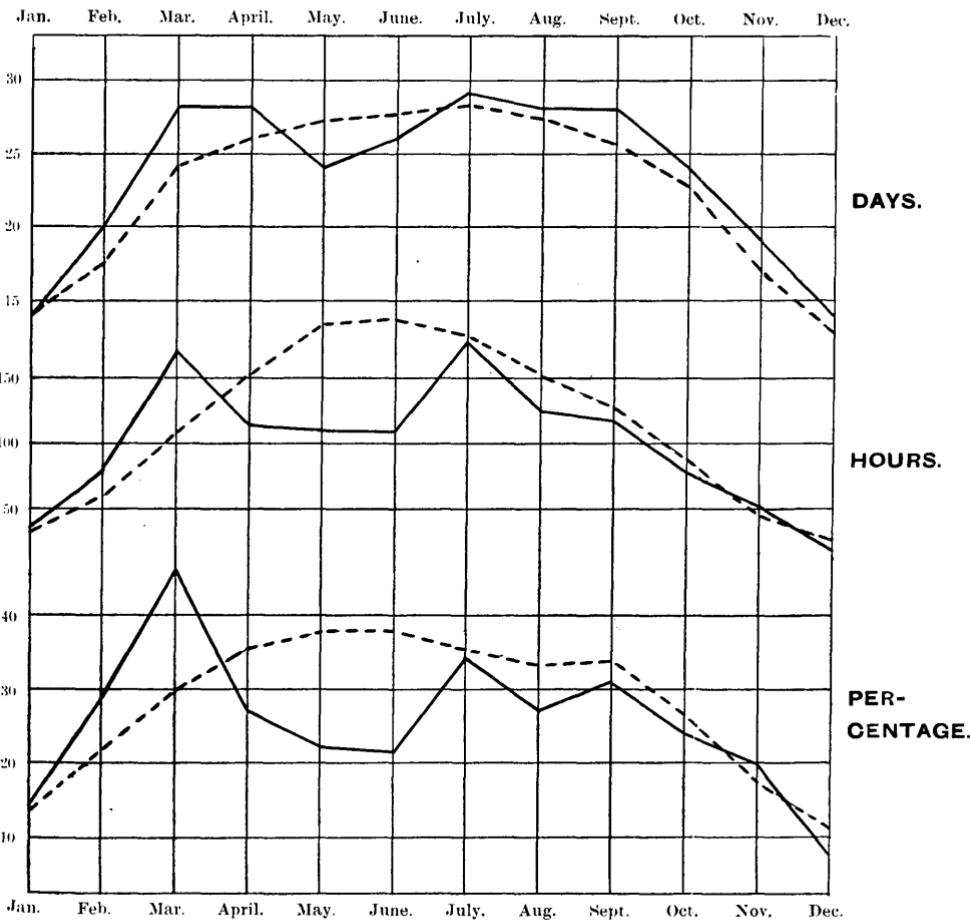

* Wind mileage 40 years only.

Recorded Sunshine of 1907.

The dotted curves show the mean values
for the last 27 years.

Annual Variation, at Stonyhurst, in four Meteorological Elements, with a comparison curve of Wolf's Smoothed Sun-Spot Relative Numbers.

The smoothed (dotted) curves are obtained from the means of five successive numbers which are themselves the means of five successive original readings.
